(57) **ABSTRACT**

A lighting device includes an outer body having a base, a medial portion, and an upper portion. The lighting device may also include an electronic device carrying assembly to carry an assembly base, an assembly top, a heat sink that matingly engages a portion of the assembly top, and a driver circuit. The assembly top may comprise a bottom portion, sidewalls, and a top portion. The bottom portion of the assembly top may include an assembly base connector member that may pivotally engage a portion of the assembly base. The electronic device carrying assembly may be configured to rotate about a first rotational axis and second rotational axis. The first and second rotational axes may be perpendicular to one another.

ROTATABLE LIGHTING DEVICE**RELATED APPLICATIONS**

This application is a continuation-in-part of U.S. patent application Ser. No. 13/792,986 titled Rotatable Lighting Device filed Mar. 11, 2013. Additionally, this application is related to U.S. patent application Ser. No. 13/765,256 titled Rotatable Lighting Fixture filed Feb. 12, 2013 which, in turn, claims the benefit under 35 U.S.C. §119(e) of U.S. Provisional Patent Application Ser. No. 61/643,312 titled Rotatable Lighting Fixture filed May 6, 2012, the entire contents of each of which are incorporated herein by reference. This application is also related to U.S. patent application Ser. No. 13/739,893 titled Tunable Lighting Apparatus filed Jan. 11, 2013, and U.S. patent application Ser. No. 13/832,900 titled Luminaire with Modular Cooling System and Associated Methods filed Mar. 15, 2013, the entire contents of which are incorporated herein.

FIELD OF THE INVENTION

The present invention relates to the fields of lighting devices and, more specifically, to canister light fixtures and lighting devices that are rotatable and emit light in different beam angles and amounts, and associated methods.

BACKGROUND OF THE INVENTION

The majority of lighting devices are fixed, meaning they cannot be adjusted to direct light emitted therefrom, thus changing the area illuminated. Of those lighting devices that can be adjusted, many require a user to manually move components of the lighting device to direct the lighting device, thus changing the area illuminated. There are some lighting fixtures that permit mechanized adjustment of the direction of the lighting device, but many of those mechanized devices are limited in their range of motion and often occupy large volumes. Accordingly, there is a long felt need for a lighting fixture that will matingly engage with existing fixtures and permits a wide range of motion to direct light while not occupying an inordinate volume of space.

Lighting technologies such as light-emitting diodes (LEDs) offer significant advantages over incandescent and fluorescent lamps. These advantages include, but are not limited to, better lighting quality, longer operating life, and lower energy consumption. The majority of LED lighting devices include LEDs that are configured together on a single plane or on a single board and emit light in one beam angle. There are some lighting devices that permit light to be emitted in more than one beam angle, but many of those devices are limited in the amount of light they emit. Accordingly, there is a long felt need for a lighting device that emits light in multiple beam angles and where the amount of light emitted is not as limited.

U.S. Pat. No. 8,172,436 to Coleman et al. discloses an LED lighting assembly that rotates by means of a pivot post and base system. The lighting assembly does not include more than one means of rotation, however, and it does not include LEDs on multiple planes which may allow light to be emitted in multiple beam angles and in various amounts. Furthermore, the lighting assembly does not have a base that allows it to matingly engage with a light fixture or socket.

U.S. Pat. No. 7,618,150 to Tseng-Lu Chien discloses an LED lighting device that includes an adjustable angle function and includes multiple LED units. This device allows light to be emitted at varied beam angles, but may not allow for an

increase or a decrease in the amount of light emitted and may not be rotational about any axis or multiple axes.

This background information is provided to reveal information believed by the applicant to be of possible relevance to the present invention. No admission is necessarily intended, nor should be construed, that any of the preceding information constitutes prior art against the present invention.

SUMMARY OF THE INVENTION

In view of the foregoing, it is therefore an object of the present invention to provide an improved LED-based lamp for use in a space-limited lamp enclosure, such as a can light fixture, for example. The embodiments of the lighting device according to the present invention advantageously allow for emission of light in a number of directions or angles and with varied amounts of light. The lighting device according to an embodiment of the present invention also advantageously provides ease of installation.

With the above in mind, the present invention is directed to a lighting device that includes an outer body having a base, a medial portion, and an upper portion. The lighting device may also include an electronic device carrying assembly. The electronic device carrying assembly may include an assembly base that is carried by the medial portion of the outer body. The electronic device carrying assembly may also include an assembly top comprising a bottom portion, sidewalls, and a top portion. The bottom portion of the assembly top may include an assembly base connector member that pivotally engages a portion of the assembly base. The electronic device carrying assembly may further include a heat sink that matingly engages a portion of the assembly top, and a driver circuit.

The electronic device carrying assembly may be configured to rotate about a first rotational axis defined by a vertical axis of the lighting device that passes through a medial portion of the base of the outer body. The electronic device carrying assembly may further be configured to pivot about a second rotational axis defined by a horizontal axis passing through a medial portion of the assembly base connector member of the assembly top. Additionally, the first and second rotational axes may be about perpendicular to one another.

The lighting device according to an embodiment of the present invention also includes an electronic device carried by the electronic device carrying assembly and/or the outer body. The electronic device may, for example, be a light source. The light source may include a plurality of light emitting diodes configured to emit light that combines to form a white light. The light source may also be configured to emit light within a wavelength range corresponding to at least one of the ultraviolet spectrum, the infrared spectrum, and the visible spectrum.

In some embodiments of the present invention, the electronic device may include a first electronic device and a second electronic device. In such embodiments, the second electronic device may include a light source and may be carried by the outer body in a position generally towards the base relative to the first electronic device and/or the electronic device carrying assembly adjacent the first electronic device. A light channeling device may be configured to direct light emitted by the light source so as not to be incident upon the first electronic device. Furthermore, light generated from the light source may be directed to a lens by the light channeling device.

In other embodiments of the present invention, the first electronic device and the second electronic device may both

include a light source. The light emitted by the first electronic device and the second electronic device may combine to form a combined light. The combined light may have a center beam and a gradient, and the center beam may have a greater brightness than the gradient.

Either or both of the amount of light and the type of light emitted by the second electronic device may be variable dependent upon either or both of the amount of light and the type of light emitted by the first electronic device. The amount of light and the type of light emitted by the first electronic device may be variable dependent upon either or both of the amount of light and the type of light emitted by the second electronic device.

The electronic device may include a communication device that is electrically coupled to the driver circuit. A rotation mechanism may be configured to rotate the electronic device carrying assembly about either or both of the first and second rotational axes. The communication device may be any one (or combination) of a wireless communication device, a radio device, a bluetooth device, a computer network device, a visible light communication device, a video device, a visual display device, and an acoustic device.

The lighting device according to an embodiment of the present invention may include a rotation mechanism. The rotation mechanism may include a first rotation mechanism configured to rotate the electronic device carrying assembly about the first rotational axis, and a second rotation mechanism configured to rotate the electronic device carrying assembly about the second rotational axis. The first and second rotation mechanisms may be selected from the group consisting of an AC motor, a DC motor, an electrostatic motor, a servo motor, a stepper motor, an actuator, a hydraulic motor, a pneumatic motor, an electromagnet, and a permanent magnet.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a perspective view of a lighting device according to an embodiment of the present invention.

FIG. 2 is a perspective view of the lighting device illustrated in FIG. 1.

FIG. 3A is a perspective view of a portion of the lighting device illustrated in FIG. 1.

FIG. 3B is a perspective view of a portion of the lighting device illustrated in FIG. 1.

FIG. 4 is a perspective view of a lighting device according to another embodiment of the present invention.

FIG. 5 is a side elevation schematic view of the lighting device illustrated in FIG. 4.

FIG. 6 is a side elevation view of a portion of the lighting device illustrated in FIG. 4.

FIG. 7 is a perspective view of a lighting device according to another embodiment of the present invention.

FIG. 8 is a side elevation schematic view of the lighting device illustrated in FIG. 7.

FIG. 9 is a side elevation view of a portion of the lighting device illustrated in FIG. 7.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The present invention will now be described fully herein-after with reference to the accompanying drawings, in which preferred embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are pro-

vided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Those of ordinary skill in the art will realize that the following embodiments of the present invention are only illustrative and are not intended to be limiting in any way. Other embodiments of the present invention will readily suggest themselves to such skilled persons having the benefit of this disclosure. Additionally, like numbers refer to like elements throughout. Prime notations are used to reference similar elements in alternate embodiments.

Throughout this disclosure, the present invention may be referred to as relating to luminaires, digital lighting, and light-emitting diodes (LEDs). Those skilled in the art will appreciate that this terminology is only illustrative and does not affect the scope of the invention. For instance, the present invention may just as easily relate to lasers or other digital lighting technologies. Additionally, a person of skill in the art will appreciate that the use of LEDs within this disclosure is not intended to be limited to any specific form of LED, and should be read to apply to light emitting semiconductors in general. Accordingly, skilled artisans should not view the following disclosure as limited to any particular light emitting semiconductor device, and should read the following disclosure broadly with respect to the same.

Although the following detailed description contains many specifics for the purposes of illustration, anyone of ordinary skill in the art will appreciate that many variations and alterations to the following details are within the scope of the invention. Accordingly, the following embodiments of the invention are set forth without any loss of generality to, and without imposing limitations upon, the claimed invention.

In this detailed description of the present invention, a person skilled in the art should note that directional terms, such as “above,” “below,” “upper,” “lower,” and other like terms are used for the convenience of the reader in reference to the drawings. Also, a person skilled in the art should notice this description may contain other terminology to convey position, orientation, and direction without departing from the principles of the present invention. The terms pivot and rotation are often used interchangeably and should not be considered limiting in any way. Those skilled in the art will appreciate that many variations and alterations to the descriptions contained herein are within the scope of the invention.

In this detailed description, a person skilled in the art should note that quantitative qualifying terms such as “generally,” “substantially,” “mostly,” and other terms are used, in general, to mean that the referred to object, characteristic, or quality constitutes a majority of the subject of the reference. More specifically, the terms “substantially horizontal” and “substantially perpendicular” are used, in general, to mean that the referred to plane is nearly, close to, or mostly horizontal or nearly, close to, or mostly perpendicular depending on the context. The meaning of any of these terms is dependent upon the context within which it is used, and the meaning may be expressly modified.

Furthermore, in this detailed description, a person skilled in the art should note that quantitative qualifying terms such as “about” or “nearly” and other terms are used, in general, to mean that the referred to object, characteristic, or quality is close to the subject of the reference. More specifically, the term “about 180 degrees” is used, in general, to mean that the referred to amount of rotation or angle of rotation is nearly, close to, or mostly 180 degrees depending on the context, but could vary by less than one, one, or multiple degrees. The meaning of any of these terms is dependent upon the context within which it is used, and the meaning may be expressly modified.

5

Referring to FIGS. 1-6, a lighting device **100** according to an embodiment of the present invention is now described in detail. Throughout this disclosure, the present invention may be referred to as a lighting device **100**, a lighting system, an LED lighting system, a lamp system, a lamp, a luminaire, a device, a system, a product, and a method. Those skilled in the art will appreciate that this terminology is only illustrative and does not affect the scope of the invention.

According to an embodiment of the present invention, as depicted, for example, in FIGS. 1-3B, the lighting device **100** may include an outer body **110**, a light source carrying assembly **120**, a lens **130**, and a driver circuit **141**. The lighting device **100** may further include a second driver circuit **142**, a communication device **143**, a channeling device **150**, and a rotation mechanism **170**. The outer body **110** may include a base **112**, a medial portion **114**, an upper portion **116**, and a plurality of ribs **118**. The plurality of ribs **118** may provide support for the lighting device **100** and may carry the channeling device **150** as described herein.

The light source **121** (as well as the second light source **122**, which is only present in an alternate embodiment of the invention, as illustrated, for example, in FIGS. 4-6) may be carried by the outer body **110** or the light source carrying assembly **120**. The second light source **122**, illustrated, for example, in FIG. 4, may be positioned generally closer to the base **112** relative to the light source **121**. The second light source **122** may also be carried by the outer body **110** or the light source carrying assembly **120** and be positioned generally closer to the base **112** relative to the light source **121** and the light emitted by the second light source **122** may be guided, directed, redirected, channeled, or moved by the channeling device **150** to the upper portion **116** or the assembly top **124**. The second light source **122** may also be positioned in a generally annularly formation about the light source **121** or along the upper portion **116**. In some embodiments, the upper portion **116** and/or the assembly top **124** may include a diffusing element. In other words, in the preferred embodiment of the invention, the light source **121** may be positioned along a centrally positioned portion of the lighting device **100**, and the second light source **122** may be positioned along the circumference, or an outer peripheral portion, of the outer body **110** of the lighting device **100**. Those skilled in the art will readily appreciate that the configuration of the light source **121** and the second light source **122** may be any configuration, and that the configurations described above are exemplary configurations, and not meant to be limiting in any way.

The light source carrying assembly **120** may comprise an assembly base **123**, an assembly top **124**, and a heat sink **125**. The assembly base **123** may be carried by the medial portion **114** of the outer body **110**. The assembly top **124** may comprise a bottom portion **126**, sidewalls **127**, and a top portion **128**. The bottom portion **126** may include an assembly base connector member **129** that pivotally or rotationally engages a portion of the assembly base **123**. The lighting device **100** may include one or more heat sinks **125**, and portions of the heat sink **125** may include fins. The light source **121** and the second light source **122** may emit light which may produce heat. The heat sink **125** may provide surface area to allow heat to travel away from the light source **121** and the second light source **122**, thereby cooling the light source **121** and the second light source **122**. Removing heat from the light source **121** and the second light source **122** may enhance the life of the light source **121**, the second light source **122**, and the lighting device **100** in general.

The heat sink **125** may be configured to extend substantially the length of the outer body and the fins may be con-

6

figured to extend substantially the length of the heat sink **125**. Those skilled in the art will appreciate that the present invention contemplates the use of fins that extend any distance and may project radially outward from the heat sink **125**, and that the disclosed heat sink **125** that includes fins that extend substantially the length thereof is not meant to be limiting in any way. The fins may increase the surface area of the heat sink **125** and may permit thermal fluid flow between each fin, thereby enhancing the cooling capability of the heat sink **125**. The plurality of ribs **118** may also allow additional thermal fluid flow between each rib **118**, thereby enhancing the cooling capability of the heat sink **125**. Additional details and information regarding the cooling function of heat sinks with respect to lighting devices are provided in U.S. Provisional Patent Application Ser. No. 61/715,075 titled Lighting Device with Integrally Molded Cooling System and Associated Methods filed on Oct. 17, 2012

The lens **130** may attach to the outer body **110**, the upper portion **116**, the assembly top **124**, and/or the top portion **128**. Specifically, the lens **130** may form an interference fit with the outer body **110**, the upper portion **116**, the assembly top **124**, and/or the top portion **128**. The interference fit preferably provides sufficient strength to carry the lens **130**. Optionally, the lens **130** may be attached to the outer body **110**, the upper portion **116**, the assembly top **124**, and/or the top portion **128** through the use of an adhesive, glue, or any other attachment method known in the art. As another further option, the lens **130** may include structural supports or other features to enhance stability of the lens and to enhance clarity and brightness of the light source **121**.

Referring to FIGS. 2 and 4-6, the lens **130** may be configured to interact with light emitted by the light source **121** and/or the second light source **122** to refract, reflect, or otherwise redirect incident light. Accordingly, the light source **121** and/or the second light source **122** may be disposed such that light emitted therefrom is incident upon the lens **130**. The lens **130** may be formed in any shape to impart a desired refraction. In the present embodiment, the lens **130** has a generally flat geometry. Furthermore, the lens **130** may be formed of any material with transparent or translucent properties that comport with the desired refraction to be performed by the lens **130**. The lighting device **100** may include multiple lenses **130**. In some embodiments of the lighting device **100**, a secondary lens **131** can be included and may attach to the outer body **110**, the upper portion **116**, the assembly top **124**, and/or the top portion **128**. The secondary lens **131** may be configured to interact with light emitted by the second light source **122** to refract, reflect, or otherwise redirect incident light.

The light source **121** and the second light source **122** may include any device capable of emitting light. The light source **121** and the light source **122** may, for example and without limitation, include incandescent lights, halogens, fluorescents (including compact-fluorescents), high-intensity discharges, light emitting semiconductors, such as light-emitting diodes (LEDs), lasers, and any other light-emitting device known in the art. In some embodiments of the present invention, the light source **121** and the second light source **122** are an LED package. In some further embodiments, the LED package may include a plurality of LEDs and a circuit board.

Referring now to FIGS. 1, 2, and 5, the heat sink **125** may mately engage a portion of the assembly top **124**. The driver circuit **141** may be electrically coupled to at least one of the light source **121**, the second light source **122**, and the base **112**. The second driver circuit **142** may be electrically coupled to the second light source **122**, the driver circuit **141**,

and/or the communication device **143**. The communication device **143** may be electrically coupled to the driver circuit **141**, the second driver circuit **142**, and/or the rotation mechanism **170**. The communication device **143** may be a wireless communication device. The communication device **143** may be a radio device, a computer network device, a visible light device, a video device, a visual display device, an acoustic device, or any other device known in the art that provides wireless communication. Those skilled in the art will appreciate that a communication device **143** being incorporated into the lighting device **100** advantageously allows for the lighting device **100** to be remotely operated and/or monitored, if so desired by a user. As illustrated in FIG. 5, for example, a remote control **144** may be used to rotate and/or pivot the lighting device **100**. The remote control **144** may also be used to adjust the amount and the beam angle of the light emitted from the light source **121** and/or the second light source **122**. Additional details relating to communication devices incorporated into a lighting device are provided in U.S. patent application Ser. No. 13/403,531 titled Configurable Environmental Condition Sensing Luminaire System and Associated Methods filed on Feb. 23, 2012, which, in turn, claims the benefit of U.S. Provisional Patent Application Ser. No. 61/486,316 titled Motion Detecting Security Light and Associated Methods filed on May 15, 2011, as well as U.S. Provisional Patent Application Ser. No. 61/486,314 titled Wireless Lighting Device and Associated Methods filed on May 15, 2011, and U.S. Provisional Patent Application Ser. No. 61/486,322 titled Variable Load Power Supply filed on May 15, 2011, the entire contents of each of which are incorporated by reference.

Referring now to FIGS. 1-6, the light source carrying assembly **120** may be configured to rotate about a first rotational axis **161** defined by a vertical axis of the lighting device **100** that passes through a centrally positioned portion of the base **112** of the outer body **110**. The first rotational axis **161** is illustratively drawn as a dashed line in FIGS. 1, 2, 3B, 4, 5, and 6. More specifically, the first rotational axis **161** preferably longitudinally passes through the centrally positioned portion of the lighting device. As perhaps best illustrated, for example, in FIG. 4, the first rotational axis **161** may be centrally located between the light source **121**. Although the first rotational axis **161** is displayed as centrally passing between the plurality of LEDs that make up the light source **121**, those skilled in the art will readily appreciate that this is simply exemplary in nature, and the first rotational axis **161** may be positioned anywhere on the lighting device **100** that allows for the light source carrying assembly **120** to be rotated as described herein.

The light source carrying assembly **120** may be further configured to pivot about a second rotational axis **162** defined by a horizontal axis passing through a centrally positioned portion of the assembly base connector member **129** of the assembly top **124**. The second rotational axis **162** is perhaps best illustrated in FIGS. 1, 3A, 3B, 5, and 6. More specifically, the second rotational axis **162** preferably latitudinally passes through a medial portion of the assembly base connector **129** (which is discussed in greater detail below) to advantageously allow the lighting device **100** to be pivotally positioned about the second rotational axis **162**. Although the second rotational axis **162** is displayed as centrally passing through the assembly base connector **129**, those skilled in the art will readily appreciate that this is simply exemplary in nature, and the second rotational axis **162** may be positioned anywhere on the lighting device **100** that allows for the light source **121** and the second light source **122** to be readily pivoted as may be desired by a user.

The first and second rotational axes **161**, **162** may be perpendicular to one another. In noting, however, that the first and second rotational axes **161**, **162** may be perpendicular to one another, those skilled in the art will appreciate that the first and second rotational axes **161**, **162** may be substantially perpendicular to one another while still accomplishing the goals, features and objectives according to the present invention. The configuration of the first and second rotational axes **161**, **162** allows for the lighting device **100** of the present invention to readily rotate and pivot so that light emitted from the light source **121** and the second light source **122** propagates substantially below a plane defined by a surface portion of the upper portion **116** of the outer body **110**. More particularly, and by way of example, light emitted from the light source **121** and the second light source **122** may be emitted in a lower hemisphere, i.e., substantially below a plane formed by an end portion of the outer body **110**. In the figures, the end portion of the outer body **110** is considered the annularly shaped portion adjacent the light source **121**. Those skilled in the art will appreciate, however, that the light emitted by the light source **121** and the second light source **122** may be emitted below any plane as defined during construction of the lighting device **100** and in any direction due to the configuration of the first and second rotational axes **161**, **162**.

Although it is preferable for the light from the light source **121** and the second light source **122** to be emitted in a generally downward direction, i.e., in a direction opposite the base, those skilled in the art will appreciate that the light may shine outwardly from the light source carrying assembly **120** in an opposite direction through various openings, and also continue to emit through the openings formed in the outer body **110**. This may advantageously allow for the lighting device **100** according to embodiments of the present invention to provide various lighting effects that may be desirable to a user.

In one embodiment of the invention, the assembly base **123** may be configured to rotate about the first rotational axis **161** resulting in the rotation of the light source carrying assembly **120**. The assembly base connector member **129** may be configured to pivotally engage the assembly base **123** resulting in the pivoting of the light source carrying assembly **120**.

As perhaps best illustrated in FIGS. 1, 3A, 3B, 5, and 6, in another embodiment of the invention, the assembly base **123** may be attached to the outer body **110**. The assembly base connector member **129** may be configured to rotate and/or pivot about the first and second rotational axes **161**, **162** resulting in the rotating and/or pivoting of the light source carrying assembly **120**.

As illustrated in FIGS. 1-6, the rotation mechanism may be configured to rotate the light source carrying assembly **120** about either or both of the first and second rotational axes **161**, **162**. The rotation mechanism **170** may be provided by a first rotation mechanism **171** and a second rotation mechanism **172**. The first rotation mechanism **171** may be configured to rotate the light source carrying assembly **120** about the first rotational axis **161**. The second rotation mechanism **172** may be configured to pivot the light source carrying member **120** about the second rotational axis **162**. The rotation mechanism **170** and the first and second rotation mechanisms **171**, **172** may be provided by an AC motor, a DC motor, an electrostatic motor, a servo motor, a stepper motor, an actuator, a hydraulic motor, a pneumatic motor, an electromagnet, and/or a permanent magnet. The skilled artisan will appreciate that any device suitable to cause rotation and pivoting about the first and second rotational axes **161**, **162** may be used as the rotation mechanism **170** and the first and second rotation mechanisms **171**, **172**, without limitation. The first and sec-

ond rotation mechanisms **171**, **172** may be provided by the same or different devices and may also include any other device that may impart a rotational, pivotal, or other similar action on the light source carrying member **120**.

As indicated above, and with reference to FIGS. **1**, **2**, **4**, **5**, and **6**, the light source **121** may be positionable such that light emitted by the light source **121** propagates substantially below a plane defined by a surface portion of the upper portion **116** of the outer body **110**. The light source **121** may be configured to emit light in at least one of a first and second beam angle. The second light source **122** may also be configured to emit light in at least one of the first and second beam angle. The channeling device **150** of the lighting device **100** according to an embodiment of the present invention may direct light emitted from the second light source **122** to the lens **130** so as not to be incident upon the light source **121**. The channeling device may be carried by the plurality of ribs **118**. The channeling device **150** may be configured to direct light emitted by the second light source **122** to an area adjacent an outer edge of the light source **121**. The channeling device **150** may also be configured to direct light emitted by the second light source **122** so as to be emitted generally annularly about the light source **121**. Those skilled in the art will appreciate that the channeling device **150** may be any structure that can guide, direct, redirect, channel, or move light, such as a light guide, and may be in any shape, location, or configuration, and that the configurations described above are exemplary configurations, and not meant to be limiting in any way.

Referring to FIGS. **4** and **6**, light emitted from the light source **121** and the second light source **122** may combine to form a combined light. The combined light may have a center beam and a gradient and the center beam may have a greater brightness than the gradient. Additional information regarding combining light to form a combined light is found in U.S. patent application Ser. No. 13/107,928, the entire contents of which are incorporated herein by reference.

Additionally, those skilled in the art will appreciate that there may be any number of light sources which may be positioned on any number of planes, above or below each other relative to the base **112**. These light sources may also emit light in any number of beam angles and combine light in any number of combinations that may increase or decrease the brightness of the center beam or gradient.

Referring now to FIGS. **1**, **2**, **4**, and **5**, those skilled in the art will appreciate that although the base **112** is illustrated as being an Edison connector attached to the outer body **110** of the lighting device **100**, the base **112** for the lighting device **100** may be provided by any type of connector that is suitable for connecting the lighting device to an external power source, including, but not limited to an Edison base, a bayonet base, a double contact bayonet base, a bi-pin, a bi-post, a wedge, and a GU10 turn and lock base.

Referring to FIGS. **1**, **3A**, **3B**, and **6**, those skilled in the art will appreciate that although the assembly base **123** is illustrated as being at least one of a pivot joint, a ball and socket joint, and a rotational joint, the connection between the outer body **110** and the light source carrying assembly **120** may be provided by any means available in the art and by one or more connections. Specifically, the connection may be provided by a pivot joint, a ball and socket joint, a rotational joint, a knuckle joint, a turnbuckle, and/or a pin joint, but any joint known in the art may be used.

As illustrated in FIGS. **1-3B**, in one embodiment, the assembly base **123** may be connected to the medial portion **114** of the outer body **110** by a rotational joint providing rotation of the assembly base **123** and the light source carrying assembly **120** in 360 degrees about the first rotational axis

161. Additionally, the assembly base **123** may be connected to the assembly base connector member **129** by a pivot joint providing up to 180 degrees of pivot of the light source carrying assembly **120** about the second rotational axis **162**.

As illustrated in FIGS. **4-6**, in another embodiment, the assembly base **123** and the assembly base connector member **129** may be connected by a ball and socket joint. This may provide 360 degrees of rotation of the light source carrying assembly **120** about the first rotational axis **161** and about 180 degrees of pivot of the light source carrying assembly **120** about the second rotational axis **162**. This configuration advantageously allows for light emitted from the light source **121** and the second light source **122** to be readily directed as described above.

Referring again to FIGS. **1**, **2**, **4**, and **5**, for example, and without limitation, the outer body **110** may be formed into any tubular shape, including a circle, ovoid, square, rectangle, triangle, or any other polygon. Referring to an embodiment of the lighting device **100**, the outer body **110** may be substantially hollow to form a circuitry chamber **140**, although not shown because it is internal to the structure, for the sake of clarity, it is shown schematically drawn in FIG. **5** with the dashed line indicating merely that it is carried by a portion of the outer body **110**, and not necessarily indicating the location of the circuitry chamber **140** or the components within. The circuitry chamber **140** may be configured to permit a power supply and electronic control devices to be positioned therein. The power supply may be configured to include an electrical contact and at least one of the driver circuit **141** and the second driver circuit **142**. The circuitry chamber **140** may present a void of sufficient geometry to permit electrical connectors, such as wires, to pass therethrough from at least one of the light source **121** and the second light source **122** to the base **112**. In order to maintain a fluid seal between the circuitry chamber **140** and the environment external to the lighting device **100**, the outer body **110** may further include a sealing member. The sealing member may include any device or material that can provide a fluid seal as described above. For example, and without limitation, the sealing member may form a fluid seal between the outer body **110** and the base **112**. Other embodiments may have the circuitry chamber **140** disposed on other parts of a cooling system and the outer body **110**.

Also for example, and without limitation, the outer body **110**, the light source carrying assembly **120**, components of the outer body **110**, and components of the light source carrying assembly **120** may be at least one of molded and over-molded, which may be individually and separately, and which may be accomplished by any molding process known in the art, including, but not limited to blow molding, sintering, compression molding, extrusion molding, injection molding, matrix molding, transfer molding, and thermoforming. The outer body **110**, the light source carrying assembly **120**, components of the outer body **110**, and components of the light source carrying assembly **120** may be attached by glue, adhesives, fasteners, screws, bolts, welding, or any other means known in the art. The power supply and other electronic circuitry may be installed into the circuitry chamber **140** of the body **110**. The power supply may include at least one of an electrical contact, the driver circuit **141**, and the second driver circuit **142**.

Additionally, and without limitation, at least one of the outer body **110**, the light source carrying assembly **120**, components of the outer body **110**, and components of the light source carrying assembly **120** may be provided by a material having a thermal conductivity=150 Watts per meter-Kelvin, a material having a thermal conductivity=200 Watts per meter-

11

Kelvin, aluminum, an aluminum alloy, a magnesium alloy, a metal loaded plastics material, a carbon loaded plastics material, a thermally conducting ceramic material, an aluminum silicon carbide material, and a plastic.

Referring now to FIGS. 7-9, another embodiment of the lighting device 100' according to the present invention is now described in greater detail. In this embodiment of the lighting device 100', an electronic device 181', or multiple electronic devices 181', are advantageously provided to enhance functionality of the lighting device 100'. The lighting device 100' according to the present embodiment of the invention may include an outer body 110' having a base 112', a medial portion 114', and an upper portion 116'. The lighting device 100' may further include a lens 130' and/or a secondary lens 131'. Those skilled in the art will appreciate that the lens 130' and/or the secondary lens 131' may include any number of lenses 130' and/or secondary lenses 131'. The lens 130' is similar to the lens 130 described in the previous embodiment of the invention, and requires no further discussion herein. The secondary lens 131' is similar to the secondary lens 131 described in the previous embodiment of the invention, and requires no further discussion herein. The outer body 110' may further include a plurality of ribs 118'. The plurality of ribs 118' are similar to the plurality of ribs 118 described in the previous embodiment of the invention, and require no further discussion herein.

The lighting device 100' according to the present embodiment of the invention may also include a rotation mechanism and an electronic device carrying assembly 120', which may be similar to the light source carrying assembly 120 as described in the previous embodiment, and may be adapted to carry an assembly base 123', an assembly top 124', a heat sink, and a driver circuit 141'. The rotation mechanism, although not illustrated in FIGS. 7-9, may be positioned within or may be carried by the outer body 110', the base 112', the medial portion 114', the upper portion 116', the electronic device carrying assembly 120', and/or the circuitry chamber 140'. For example, and without limitation, in FIG. 8, the rotation mechanism is positioned in the circuitry chamber 140' and within base 112' and the medial portion 114'.

The assembly base 123' may be carried by the medial portion 114' of the outer body. The assembly top 124' may include a bottom portion 126', sidewalls 127', and a top portion 128'. The bottom portion 126' of the assembly top 124' may include an assembly base connector member 129' that pivotally engages a portion of the assembly base 123'. The heat sink, although not illustrated in FIGS. 7-9, may matingly engage a portion of the assembly top 124'.

The electronic device carrying assembly 120' may be configured to rotate about a first rotational axis 161' defined by a vertical axis of the lighting device 100' that passes through a medial portion 114' of the base 112' of the outer body 110'. The electronic device carrying assembly 120' may be configured to pivot about a second rotational axis 162' defined by a substantially horizontal axis passing through a medial portion of the assembly base connector member 129' of the assembly top 124'. Additionally, in some embodiments, the first and second rotational axes 161', 162' may be substantially perpendicular to one another. Those skilled in the art will appreciate that there may be any number of locations where the first and second rotational axes 161', 162' may exist within the lighting device 100' that will allow the lighting device 100' to function as intended and the locations presented herein are only examples of possible locations.

The electronic device 181' that may be carried by the electronic device carrying assembly 120' or the outer body 110' and the electronic device 181' may comprise a light source.

12

More specifically, the electronic device 181' may be carried by a medial portion of the assembly top 124'. The light source may also be carried by the outer body 110' or the electronic device carrying assembly 120'. The light source may include a first and second light source 121', 122'. The light source may comprise a light emitting diode (LED) or a plurality of light emitting diodes (LEDs) that may be configured to emit light that may combine to form a white light. The light source may also be configured to emit light within a wavelength range corresponding to the ultraviolet spectrum, the infrared spectrum, or the visible spectrum.

In the present embodiment, each of the assembly base 123' and the assembly base connector member 129' may be provided by a ball-and-socket joint as described hereinabove. This may provide 360 degrees of rotation of the electronic device carrying assembly 120' about the first rotational axis 161' and about 180 degrees of pivot of the electronic device carrying assembly 120' about the second rotational axis 162'. This configuration advantageously allows for light emitted from the second light source 122' to be readily directed as described above. Furthermore, where the electronic device 181' is a light source, this configuration advantageously allows for light emitted from the light source 121' to be readily directed as described above. Furthermore, where the electronic device 181' is something other than a light source, this configuration advantageously allows for the repositioning and reorienting of the electronic device 181' as may be desirable in its operation.

As an example, and without limitation, FIGS. 7-9 illustrate that the lighting device 100', according to this embodiment of the invention, illustratively includes a plurality of electronic devices 181'. For example, the electronic devices 181' may be provided by the light source or the first and second light sources 121', 122'. The light sources 121', 122' are similar to the light sources 121, 122 described in the first embodiment of the invention, and require no further discussion herein. As further illustrated, the electronic device 181' may also be carried by the electronic device carrying assembly 120' and be provided by the first and second electronic devices 182', 183'.

The first light source 121' may be carried by the electronic device carrying assembly 120'. The second light source 122' may be carried by the outer body 110'. The amount of light or the type or characteristics of light emitted by the second light source 122' may be variable dependent upon the amount of light and/or the type of light emitted by the first light source 121' and the amount of light or the type of light emitted by the first light source 121' may be variable dependent upon the amount of light and/or the type of light emitted by the second light source 122'. As an example, the variations of light intensity may include the first light source 121' at minimum or maximum intensity combined with the second light source 122' at minimum possible intensity or even off (no intensity) or maximum intensity and the combination may include any level of intensity between no intensity and a maximum combined intensity both across the visible spectrum and at narrow wavelength ranges therewithin, as well as the IR and UV spectrums, for the first and second light source 121', 122'. The intensities of the first and second light source 121', 122' may also be reversed. As an additional example, the first light source 121' may emit light within a wavelength range corresponding to the visible spectrum, whereas the second light source 122' may emit light within a wavelength range corresponding to the ultraviolet spectrum or the infrared spectrum, or vice versa.

The electronic device 181' may include a first electronic device 182' and a second electronic device 183'. The first and second electronic devices 182', 183' may include the light

13

source, the first light source **121'**, and/or the second light source **122'**. In other words, in this embodiment of the lighting device **100'** according to the present invention, the first and second electronic devices **182'**, **183'** may be provided by any combination of light sources. Light emitted by the first light source **121'** and/or the second light source **122'** may combine to form a combined light which may have specified characteristics. The combined light may have a center beam and a gradient, and the center beam may have a greater brightness than the gradient. Additional details relating to combining light sources, center beams, and gradients incorporated into a lighting device are provided in U.S. patent application Ser. No. 13/739,893 titled Tunable Lighting Apparatus filed on Jan. 11, 2013, which, in turn, claims the benefit of U.S. Provisional Patent Application Ser. No. 61/643,299 titled Tunable Lighting Apparatus filed on May 6, 2012, the entire contents of each of which are incorporated by reference. Additionally, the light emitted by the first light source **121'** may be within a first wavelength range, and the light emitted by the second light source **122'** may be in a second wavelength range, and the combined light may be a metamer configured to be perceived as a certain color by an observer. Furthermore, the light emitted by each of the first and second light sources **121'**, **122'** may themselves be a metamer configured to be perceived as a first color, and may combine to form another metamer configured to be perceived as a second color. More information regarding the combination of wavelengths of light to form metamers, and the processes of selecting and selectively emitting said wavelengths, may be found in U.S. patent application Ser. No. 13/737,606 titled Tunable Light System and Associated Methods filed Jan. 9, 2013, U.S. patent application Ser. No. 13/775,936 titled Adaptive Light System and Associated Methods filed Feb. 25, 2013, and U.S. patent application Ser. No. 13/803,825 titled System for Generating Non-Homogenous Biologically-Adjusted Light and Associated Methods filed Mar. 14, 2013, the contents of each of which are incorporated in their entirety herein by reference.

The second electronic device **183'** may be carried by the outer body **110'** in a position generally towards the base **112'** relative to the first electronic device **182'** or it may be carried by the electronic device carrying assembly **120'** adjacent the first electronic device **182'**. A light channeling device **150'** may be configured to direct light emitted by the second electronic device **183'** so as not to be incident upon the first electronic device **182'** and the light generated from the second electronic device **183'** may be directed to the lens **130'** by the light channeling device **150'**.

Referring to FIGS. 7-9, the outer body **110'** may be substantially hollow to form a circuitry chamber **140'**, although not shown because it is internal to the structure, for the sake of clarity, it is shown schematically drawn in FIG. 8 with the dashed line indicating merely that it is carried by a portion of the outer body **110'**, and not necessarily indicating the location of the circuitry chamber **140'** or the components within. The circuitry chamber **140'** is similar to the circuitry chamber **140** described in the first embodiment of the invention, and requires no further discussion herein.

The electronic device **181'** may include a communication device **143'** that may be electrically coupled to the driver circuit **141'**. The driver circuit **141'** may be electrically coupled to the electronic device **181'**, the first electronic device **182'**, the second electronic device **183'**, the light source, the first light source **121'**, the second light source **122'**, the rotation mechanism, and/or the base **112'**. The lighting device **100'** may further include a second driver circuit **142'** electrically coupled to the driver circuit **141'**, the electronic

14

device **181'**, the first electronic device **182'**, the second electronic device **183'**, the light source, the first light source **121'**, the second light source **122'**, the rotation mechanism, and/or the base **112'**. Those skilled in the art will appreciate that there may be any number of driver circuits which may be electrically coupled to any number of other devices and/or components.

The communication device **143'** may be a wireless communication device, a radio device, a Bluetooth device, a computer network device, a cellular data communication device, a visible light communication device, a video device, a visual display device, or an acoustic device. Those skilled in the art will appreciate that there may be any number of other devices that may be carried by the lighting device **100'**, the electronic device **181'**, the first electronic device **182'**, or the second electronic device **183'**. As illustrated in FIG. 8, for example, a remote control **144'** may be used to rotate and/or pivot the lighting device **100'**.

For example, and without limitation, the communication device **143'** may receive a signal from the remote control **144'** or another device such as a cellular phone, a tablet, a computer, or a computer network. The signal may be a wireless, wired, radio, or other type of signal suitable for conducting communications. The communication device **143'** may electronically communicate with the light source, the first light source **121'**, or the second light source **122'**. Through the electronic communication provided by the communication device **143'**, the light source, the first light source **121'**, or the second light source **122'** may provide a light intensity as specified further herein.

As another example, and without limitation, the communication device **143'** may receive a signal from the remote control **144'** or another device such as a cellular phone, a tablet, a computer, or a computer network. The signal may be a wireless, wired, radio, or other type of signal suitable for carrying out communication. The signal may turn on the electronic device **181'**, the first electronic device **182'**, or the second electronic device **183'**, which may, for example, be a speaker. The electronic device **181'**, the first electronic device **182'**, or the second electronic device **183'** may further continue to receive a signal that carries data relating to an audio file, for example, thereby providing audio from a user, such as in an intercom system, or a device, such as the Internet through a computer or a radio station through a radio signal.

As yet another example, and without limitation, the communication device **143'** may receive a signal wirelessly through radio waves. The electronic device **181'**, the first electronic device **182'**, and/or the second electronic device **183'** may, for example, be a speaker and may continuously receive the signal thereby providing audio (such as streaming audio) from a radio station through the radio signal.

As yet another example, and without limitation, the communication device **143'** may receive a signal from the remote control **144'**, a cable transmission, or another device such as a cellular phone, a tablet, a computer, or a computer network. The signal may be a wireless, wired, radio, or other type of signal suitable for carrying out communication. The communication device **143'** may electronically communicate video through a visual display device or may alternatively receive video through a video device, such as a camera or video camera. In the instance of a video device, the video may be recorded in the lighting device **100'** or may be transmitted to another device, such as a cellular phone, a tablet, a computer, or a computer network. Those skilled in the art will appreciate that the communication device **143'** may be a camera that is communicatively coupled to the network, and that allows for video being captured thereby to be transmitted. The rotation

15

mechanism may be configured to rotate the electronic device carrying assembly 120' about the first and/or second rotational axes 161', 162'. Although not illustrated in FIGS. 7-9, the rotation mechanism may include a first and second rotation mechanism. The first rotation mechanism may be configured to rotate the electronic device carrying assembly 120' about the first rotational axis 161' and the second rotation mechanism may be configured to rotate the electronic device carrying assembly 120' about the second rotational axis 162'. The first rotational axis 161' may be defined by a vertical axis of the lighting device 100' that passes through a medial portion of the base 112' of the outer body 110'. The second rotational axis 162' may be defined by a horizontal axis passing through a medial portion of the assembly base connector member 129' of the assembly top 124'. The first and second rotation mechanism may be an AC motor, a DC motor, an electrostatic motor, a servo motor, a stepper motor, an actuator, a hydraulic motor, a pneumatic motor, an electromagnet, or a permanent magnet. Those skilled in the art will appreciate that there may be any number of motors and/or devices that may allow the rotation mechanism, the first rotation mechanism, or the second rotation mechanism to impart rotation on any number of components of the lighting device 100' and that the motors and devices mentioned are only examples.

As an example, and without limitation, the communication device 143' may receive a signal from the remote control 144' or another device such as a cellular phone, a tablet, a computer, or a computer network. The signal may be a wireless, wired, radio, or other type of signal suitable for carrying out communication. The communication device 143' may electronically communicate with the rotation mechanism. The rotation mechanism may cause the electronic device carrying assembly 120' to rotate about the first and/or second rotational axes 161', 162' so that light emitted from the first light source 121' or the first electronic device 182' may illuminate in a new direction.

The other elements of this embodiment of the lighting device 100' are similar to those of the first embodiment of the lighting device 100, are labeled with prime notations, and require no further discussion herein.

Some of the illustrative aspects of the present invention may be advantageous in solving the problems herein described and other problems not discussed which are discoverable by a skilled artisan.

While the above description contains much specificity, these should not be construed as limitations on the scope of any embodiment, but as exemplifications of the presented embodiments thereof. Many other ramifications and variations are possible within the teachings of the various embodiments. While the invention has been described with reference to exemplary embodiments, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted for elements thereof without departing from the scope of the invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the invention without departing from the essential scope thereof. Therefore, it is intended that the invention not be limited to the particular embodiment disclosed as the best or only mode contemplated for carrying out this invention, but that the invention will include all embodiments falling within the scope of the appended claims. Also, in the drawings and the description, there have been disclosed exemplary embodiments of the invention and, although specific terms may have been employed, they are unless otherwise stated used in a generic and descriptive sense only and not for purposes of limitation, the scope of the invention therefore not being so limited. Moreover, the use of

16

the terms first, second, etc. do not denote any order or importance, but rather the terms first, second, etc. are used to distinguish one element from another. Furthermore, the use of the terms a, an, etc. do not denote a limitation of quantity, but rather denote the presence of at least one of the referenced item.

Thus, the scope of the invention should be determined by the appended claims and their legal equivalents, and not by the examples given.

What is claimed is:

1. A lighting device comprising:

an outer body having a base, a medial portion, and an upper portion;

an electronic device carrying assembly carrying a rotatable electronic device, the electronic device carrying assembly comprising;

an assembly base that is carried by the medial portion of the outer body,

an assembly top comprising a bottom portion, sidewalls, and a top portion, the bottom portion of the assembly top including an assembly base connector member

that pivotally engages a portion of the assembly base, a heat sink that matingly engages a portion of the assembly top, and

a driver circuit; and

a non-rotatable light source carried by the outer body that is annularly formed around the rotatable electronic device;

wherein the electronic device carrying assembly is configured to rotate about a first rotational axis defined by a vertical axis of the lighting device that passes through a medial portion of the base of the outer body;

wherein the electronic device carrying assembly is configured to pivot about a second rotational axis defined by a horizontal axis passing through a medial portion of the assembly base connector member of the assembly top; and

wherein the first and second rotational axes are perpendicular to one another.

2. The lighting device according to claim 1 wherein the rotatable electronic device comprises a rotatable light source.

3. The lighting device according to claim 2 wherein the rotatable light source comprises a plurality of light emitting diodes configured to emit light that combines to form a white light.

4. The lighting device according to claim 2 wherein the non-rotatable light source is configured to emit light within a wavelength range corresponding to at least one of the ultraviolet spectrum, the infrared spectrum, and the visible spectrum.

5. The lighting device according to claim 1 wherein the rotatable electronic device comprises a first electronic device and a second electronic device.

6. The lighting device according to claim 5 wherein the non-rotatable light source is carried by at least one of the outer body in a position generally towards the base relative to the first electronic device and the electronic device carrying assembly adjacent the first electronic device; wherein a light channeling device is configured to direct light emitted by the light source so as not to be incident upon the first electronic device; and wherein the light generated from the light source is directed to a lens by the light channeling device.

7. The lighting device according to claim 5 wherein the first electronic device and the second electronic device both comprise a light source; wherein light emitted by the first electronic device and the second electronic device combines to form a combined light; wherein the combined light has a

17

center beam and a gradient; and wherein the center beam has a greater brightness than the gradient.

8. The lighting device according to claim 7 wherein at least one of the amount of light and the type of light emitted by the second electronic device is variable dependent upon at least one of the amount of light and the type of light emitted by the first electronic device; and wherein the amount of light and the type of light emitted by the first electronic device is variable dependent upon at least one of the amount of light and the type of light emitted by the second electronic device.

9. The lighting device according to claim 1 wherein the rotatable electronic device comprises a communication device that is electrically coupled to the driver circuit; and wherein a rotation mechanism is configured to rotate the electronic device carrying assembly about at least one of the first and second rotational axes.

10. The lighting device according to claim 9 wherein the communication device is selected from the group consisting of a wireless communication device, a radio device, a bluetooth device, a computer network device, a visible light communication device, a video device, a visual display device, and an acoustic device.

11. The lighting device according to claim 1 further comprising a rotation mechanism; wherein the rotation mechanism comprises a first rotation mechanism configured to rotate the electronic device carrying assembly about the first rotational axis, and a second rotation mechanism configured to rotate the electronic device carrying assembly about the second rotational axis; and wherein the first and second rotation mechanisms are selected from the group consisting of an AC motor, a DC motor, an electrostatic motor, a servo motor, a stepper motor, an actuator, a hydraulic motor, a pneumatic motor, an electromagnet, and a permanent magnet.

12. A lighting device comprising:

an electronic device carrying assembly carrying a rotatable electronic device, the electronic device carrying assembly comprising;

an assembly base that is connected to the medial portion of the outer body,

an assembly top comprising a bottom portion, sidewalls, and a top portion, the bottom portion of the assembly top including an assembly base connector member that pivotally engages a portion of the assembly base, a heat sink that engages a portion of the assembly top, a driver circuit,

an electronic device carried by a medial portion of the assembly top; and

an outer body generally circumscribing the electronic device carrying assembly and comprising a base, an upper portion, and a plurality of ribs and carrying a non-rotatable light source that is annularly formed around the rotatable electronic device;

wherein the driver circuit is electrically coupled to the rotatable electronic device, the non-rotatable light source, and the base;

wherein the electronic device carrying assembly is configured to rotate about a first rotational axis defined by a vertical axis of the lighting device that passes through a medial portion of the base of the outer body;

wherein the electronic device carrying assembly is configured to pivot about a second rotational axis defined by a horizontal axis passing through a medial portion of the assembly base connector member of the assembly top;

wherein the first and second rotational axes are perpendicular to one another; and

wherein the non-rotatable light source comprises a light emitting diode (LED).

18

13. The lighting device according to claim 12 wherein the non-rotatable light source is carried by the outer body in a position generally towards the base relative to the rotatable electronic device; wherein a light channeling device is configured to direct light emitted by the light source so as not to be incident upon the rotatable electronic device; and wherein light generated from the light source is directed to a lens by the light channeling device.

14. The lighting device according to claim 12 wherein the rotatable electronic device comprises a communication device that is electrically coupled to the driver circuit; wherein a rotation mechanism is configured to rotate the electronic device carrying assembly about at least one of the first and second rotational axes; and wherein the communication device is selected from the group consisting of a wireless communication device, a radio device, a bluetooth device, a computer network device, a visible light communication device, a video device, a visual display device, and an acoustic device.

15. The lighting device according to claim 12 further comprising a rotatable light source carried by the electronic device carrying assembly; wherein at least one of the amount of light and the type of light emitted by the non-rotatable light source is variable dependent upon at least one of the amount of light and the type of light emitted by the rotatable light source.

16. The lighting device according to claim 12 further comprising a first rotation mechanism configured to rotate the electronic device carrying assembly about the first rotational axis, and a second rotation mechanism configured to rotate the electronic device carrying assembly about the second rotational axis; and wherein the first and second rotation mechanisms are selected from the group consisting of an AC motor, a DC motor, an electrostatic motor, a servo motor, a stepper motor, an actuator, a hydraulic motor, a pneumatic motor, an electromagnet, and a permanent magnet.

17. An electronic device comprising:

an outer body having a base, a medial portion, and an upper portion;

an electronic device carrying assembly carrying a rotatable electronic device, the electronic device carrying assembly comprising;

an assembly base that is carried by the medial portion of the outer body,

an assembly top comprising a bottom portion, sidewalls, and a top portion, the bottom portion of the assembly top including an assembly base connector member that pivotally engages a portion of the assembly base, a heat sink that engages a portion of the assembly top, a driver circuit,

an electronic device carried by a medial portion of the assembly top;

a rotatable first electronic device carried by the electronic device carrying assembly;

a non-rotatable second electronic device carried by the outer body that is annularly formed around the rotatable first electronic device;

a first rotation mechanism configured to rotate the electronic device carrying assembly about a first rotational axis defined by a vertical axis of the lighting device that passes through a medial portion of the base of the outer body; and

a second rotation mechanism configured to rotate the electronic device carrying assembly about a second rotational axis defined by a horizontal axis passing through a medial portion of the assembly base connector member of the assembly top;

19

wherein the driver circuit is electrically coupled to at least one of the rotatable electronic device, the rotatable first electronic device, the non-rotatable second electronic device, the first rotation mechanism, the second rotation mechanism, and the base;

wherein the electronic device carrying assembly is configured to rotate about the first rotational axis and the second rotational axis; and

wherein the first and second rotational axes are perpendicular to one another.

18. The electronic device according to claim **17** wherein the second light source is carried by the outer body in a position generally towards the base relative to at least one of the electronic device and the first light source; wherein a light channeling device is configured to direct light emitted by the second light source so as not to be incident upon at least one of the electronic device and the first light source; and wherein light generated from the second light source is directed to a lens by the light channeling device.

20

19. The electronic device according to claim **17** wherein the electronic device comprises a communication device that is electrically coupled to the driver circuit; and wherein the communication device is selected from the group consisting of a wireless communication device, a radio device, a blue-tooth device, a computer network device, a visible light communication device, a video device, a visual display device, and an acoustic device.

20. The electronic device according to claim **17** wherein the rotatable electronic device and the non-rotatable electronic device are lighting devices and at least one of the amount of light and the type of light emitted by the non-rotatable electronic device is variable dependent upon at least one of the amount of light and the type of light emitted by the rotatable electronic device; and wherein the amount of light and the type of light emitted by the rotatable electronic device is variable dependent upon at least one of the amount of light and the type of light emitted by the non-rotatable light source.
